

Entodermal derivatives: formation of the gut, liver, and pancreas

Mike Gershon

Folding forms the gut

- Primitive gut extends from buccopharyngeal to cloacal membrane.
 - Move toward each other
- Cardiogenic mesenchyme is originally rostral, but folding brings it caudal to buccal membrane.
- Foregut and hindgut become recognizable
- Portion of yolk sac is incorporated into the embryo as bowel.
- Midgut remains open.

Cephalocaudal and lateral folding occur simultaneously

- Meeting and fusion of cranial, lateral, and caudal edges of the embryo create the primordial foregut and hindgut
 - Slow fusion of midgut-due to presence of yolk sac. Midgut remains open until week 6-connects to yolk sac via *vitelline duct*.
 - Buccopharyngeal membrane opens at 4 and cloacal membrane at 7 weeks

Flexion delimits the bowel

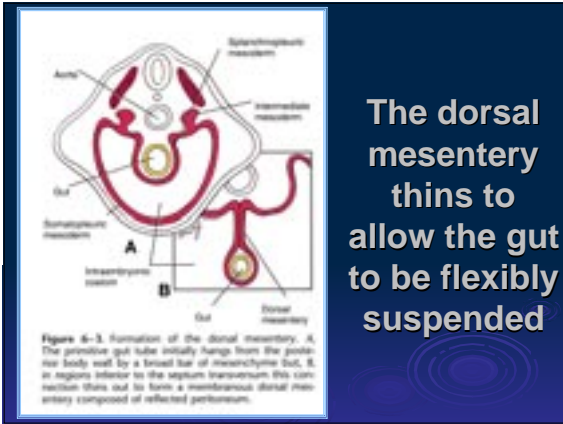

- After the gut forms, it is attached to the body wall by dorsal and ventral mesenteries; ventral is lost except in region of liver. Vetelline duct remains in umbilical cord.

Anterior-posterior and lateral folding form the primitive gut

- Embryonic disc grows faster in length than the yolk sac causing the embryo to bend.
 - Dorsal surface grows more rapidly than the ventral
- Lateral folding
 - Fusion with apposing side except in the region of the yolk sac, and allantois
- Folding brings the heart and septum transversum caudal to bucco-pharyngeal membrane.

The foregut has many derivatives

- Pharynx and its derivatives
- Lower Respiratory tract
- Esophagus
- Stomach
- Duodenum proximal to ampulla of Vater
- Liver
- Biliary Apparatus
- Pancreas

From stomach to biliary apparatus, all are supplied by the celiac artery, "the artery of the foregut."

Esophagus elongates rapidly

- Appears to grow faster at its cranial than caudal end.
- Stomach does not descend but arises from a region just caudal to septum transversum that has been fated to be stomach.
- Epithelium obliterates lumen of esophagus and is recanalized by apoptosis (week 8).
 - Failure causes polyhydramnios
 - Esophageal atresia or tracheo-esophageal fistula.
- Stomach enlarges and rotates

Rotation of the stomach forms the omental bursa

Movements of the mesentery and stomach are made possible by vacuolization due to selective apoptosis

Figure 9-4 The rotation of the stomach around its longitudinal axis coincides with vacuolization of the right side of the thick mesenteric bar that initially suspends the stomach from the posterior body wall.

Liver, biliary system and pancreas arise from the duodenum

Figure 9.6 Development of the foregut, gallbladder, biliary system, and their derivatives. The foregut gives rise to the esophagus, stomach, and duodenum. The foregut also gives rise to the liver, gallbladder, and biliary system. The foregut also gives rise to the pancreas. The foregut also gives rise to the lungs and trachea. The foregut also gives rise to the thyroid gland. The foregut also gives rise to the thymus. The foregut also gives rise to the parathyroid glands. The foregut also gives rise to the adrenal medulla. The foregut also gives rise to the pineal gland. The foregut also gives rise to the pituitary gland. The foregut also gives rise to the hypothalamus. The foregut also gives rise to the optic chiasm. The foregut also gives rise to the optic nerves. The foregut also gives rise to the optic tectum. The foregut also gives rise to the optic tract. The foregut also gives rise to the optic chiasm. The foregut also gives rise to the optic nerves. The foregut also gives rise to the optic tectum. The foregut also gives rise to the optic tract.

Hepatic diverticulum grows from the duodenum into the ventral mesentery

- > Begins ~ week 4
- > Divides into cranial and caudal buds.
- > Cranial bud grows faster and becomes the hepatic parenchyma;
 - Hematopoietic colonists arrive ~ week 6
- > Caudal bud gives rise to the biliary system.

Ventral mesentery forms falciform ligament, hepatic peritoneum, and lesser omentum

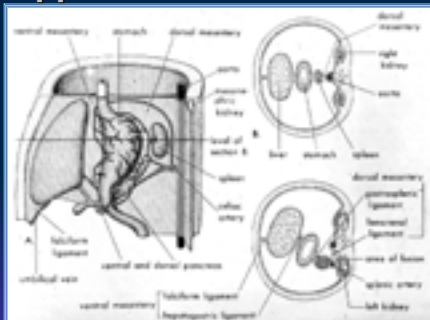

Figure 9-8. Formation of the liver and associated membranes. As the liver bud grows into the ventral mesentery, its expanding rim makes direct contact with the developing diaphragm. The ventral mesentery that encloses the growing liver bud differentiates into the visceral peritoneum of the liver, which is reflected onto the diaphragm. This fold of reflection, which encloses the area where the liver directly contacts the diaphragm (the bare area), becomes the coronary ligament. The remnant of ventral mesentery connecting the liver with the anterior body wall becomes the falciform ligament, whereas the ventral mesentery between the liver and lesser curvature of the stomach forms the lesser omentum.

Ventral mesogastrium supports liver and stomach

Rotation of the stomach shapes the pancreas

- ▶ Pancreas arises from dorsal and ventral buds.
- ▶ Rotation brings ventral to dorsal bud.
- ▶ Buds fuse.
 - Ventral duct becomes the main pancreatic duct but the dorsal bud forms most of the pancreas
 - Ventral bud forms only the uncinus process and inferior part of the head of the pancreas.

Aberrant rotation causes an annular pancreas

Figure 9-3. The ventral pancreas may consist of two lobes. If the lobes rotate around the duodenum in opposite directions to face with the dorsal pancreatic bud, an annular pancreas is formed.

Figure 9-2 Structure of the gut tube. The foregut consists of the pharynx, located superior to the respiratory diverticulum, the thoracic esophagus, and the abdominal foregut. The abdominal foregut forms the distal esophagus, stomach, and about half of the duodenum and gives rise to the liver, the gallbladder, the pancreas, and the associated ducts. The midgut forms half of the duodenum, the jejunum and ileum, the ascending colon, and about two-thirds of the transverse colon. The hindgut forms one-third of the transverse colon, the descending colon and sigmoid colon, and the upper two-thirds of the anal canal. The abdominal esophagus, stomach, and superior part of the duodenum are supplied by dorsal and ventral mesenteries; the abdominal gut tube ventral to the inferior vena cava is suspended in the abdominal cavity by a dorsal mesentery only.

Derivatives of the midgut

- Small intestine (except for the proximal duodenum).
- Cecum
- Appendix
- Ascending colon
- Right 1/2 to 2/3 of the proximal transverse colon
- All are supplied by the superior mesenteric artery ("the artery of the midgut")

The midgut grows rapidly and herniates into the umbilical cord

Week 6

The midgut rotates around an axis of the superior mesenteric artery:

1. 90°
2. 180°

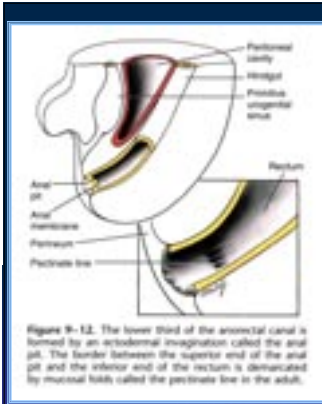

Midgut hernia reduced at week 10.

Rotation of the midgut

- 1. Cranial and caudal loop form.
- 2. Cranial growth >>> caudal growth.
- 3. Apex of loop is vitelline duct.
- 4. Cranial loop moves to right and caudal loop to left (90° counterclockwise).
- 4. Reduction of midgut hernia with rotation a further 180°.
 - Brings cecum to right
 - Moves down
 - Becomes secondarily retroperitoneal.

Loops of bowel fuse with the body wall and become secondarily retroperitoneal

Figure 9-4 The distinction between intraperitoneal, retroperitoneal, and secondarily retroperitoneal parts of the viscera. A, Viscera suspended within the peritoneal cavity by a mesentery are called intraperitoneal, whereas organs embedded in the body wall and covered by peritoneum are called retroperitoneal. B, The mesentery suspending some intraperitoneal organs degenerates or fuses to the body wall, and organs fuse with the body wall. These organs are then called secondarily retroperitoneal.

Hindgut forms superior 2/3 of rectal canal; proctodeum forms lower 1/3; divided at pectinate line

Never forget the pectinate line

If anything can go wrong it will; anorectal malformations

The END

Have a nice day!

Figures 9-23. Fate of the allantois. A, Normally, the allantois becomes occluded to form the urachus or median umbilical ligament of the adult. Very rarely, parts of the allantois may remain patent, producing (B) a urachal fistula, (C) a urachal sinus, (D) a urachal diverticulum, or (E) a urachal cyst.

**Table 9-2
Derivatives of the Septum Transversum**

REGIONS OF SEPTUM TRANSVERSUM	DERIVATIVES
Cranial region	Central tendon of the diaphragm
Central mesenchyme	Myocytes of the diaphragmatic membranes
Caudal region (central mesentery)	Hematopoietic cells of liver
	Falciform ligament
	Visceral peritoneum of the liver, including the coronary ligament
	Visceral peritoneum of the gallbladder
	Lower oesophagus, including the hepatoduodenal and hepatogastric ligaments

**Table 9-1
The Derivatives of the Primitive Gut Tube**

REGIONS OF THE DIFFERENTIATED GUT TUBE	ACCESSORY ORGANS DERIVED FROM THE GUT TUBE ENDODERM
Foregut	
Thyroid	Pharyngeal pouch derivatives (see Ch. 12)
Thoracic esophagus	Lungs
Abdominal esophagus	
Stomach	
Superior half of duodenum (superior to the ampulla of Vater)	Liver parenchyma and hepatic duct epithelium Gallbladder, cystic duct, and common bile duct Dorsal and ventral pancreatic buds (islets cells and pancreatic duct epithelium, probably also pancreatic endocrine cells)
Midgut	
Inferior half of duodenum	
Jejunum	
Ileum	
Cecum	
Appendix	
Ascending colon	
Right two thirds of transverse colon	
Midgut	
Left one third of transverse colon	
Descending colon	
Sigmoid colon	
Rectum	Urogenital sinus and derivatives (see Ch. 16)
