

**Part I. Kidney development**  
**Part II. UGT development**

**Cathy Mendelsohn-clm20@columbia.edu**  
**Human Development**  
**Spring 2009**

nephrons in the kidney generate urine that is propelled to the ureters and then to the bladder for storage and excretion

## **The Urinary outflow tract:**

- **monitors and regulates extra-cellular fluids**
- **excretes harmful substances in urine, including nitrogenous wastes (urea)**
- **returns useful substances to bloodstream**
- **maintain balance of water, electrolytes (salts), acids, and pH in the body fluids**

The human kidney has about 500,000 nephrons that filter and modify the blood

**glomeruli**

**tubules**

At birth the collecting duct system has tens of thousands of branches

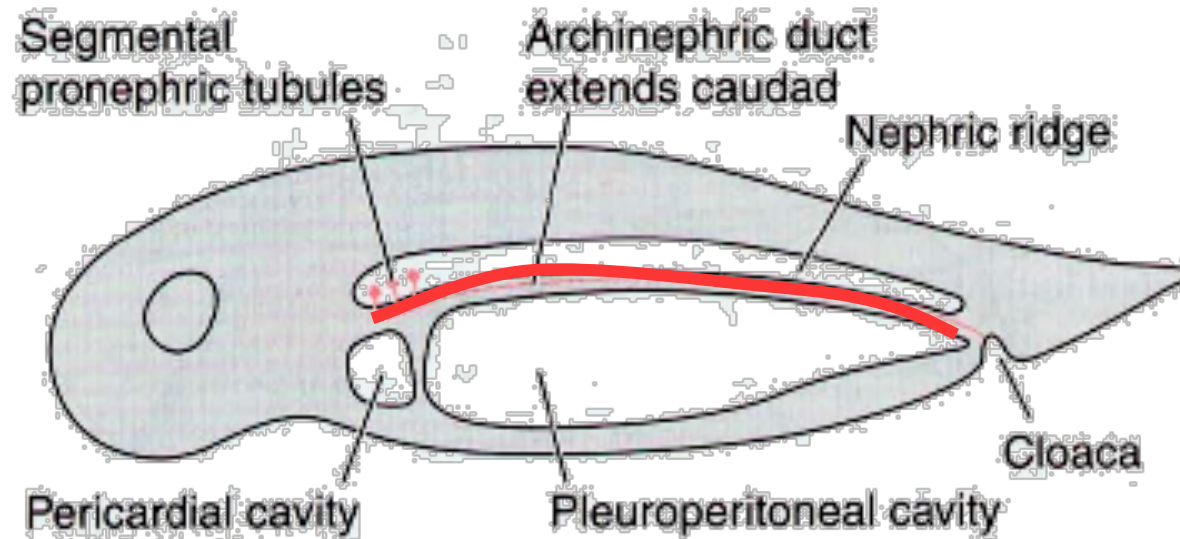

The papilla contains bundles of nephrons and CD

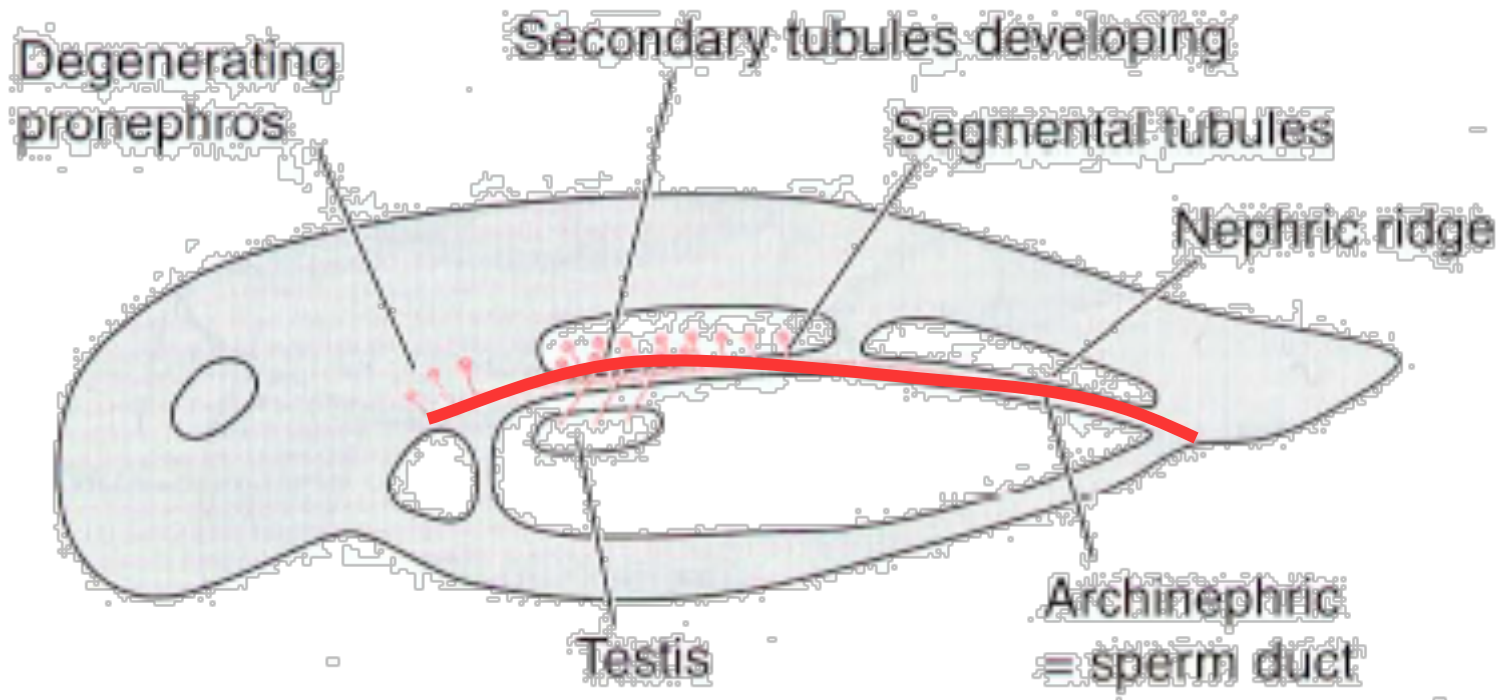

The urogenital system derives predominantly from intermediate mesoderm

## pronephros in an early embryo

The pronephros is a functional kidney in some species  
but regresses in mammals

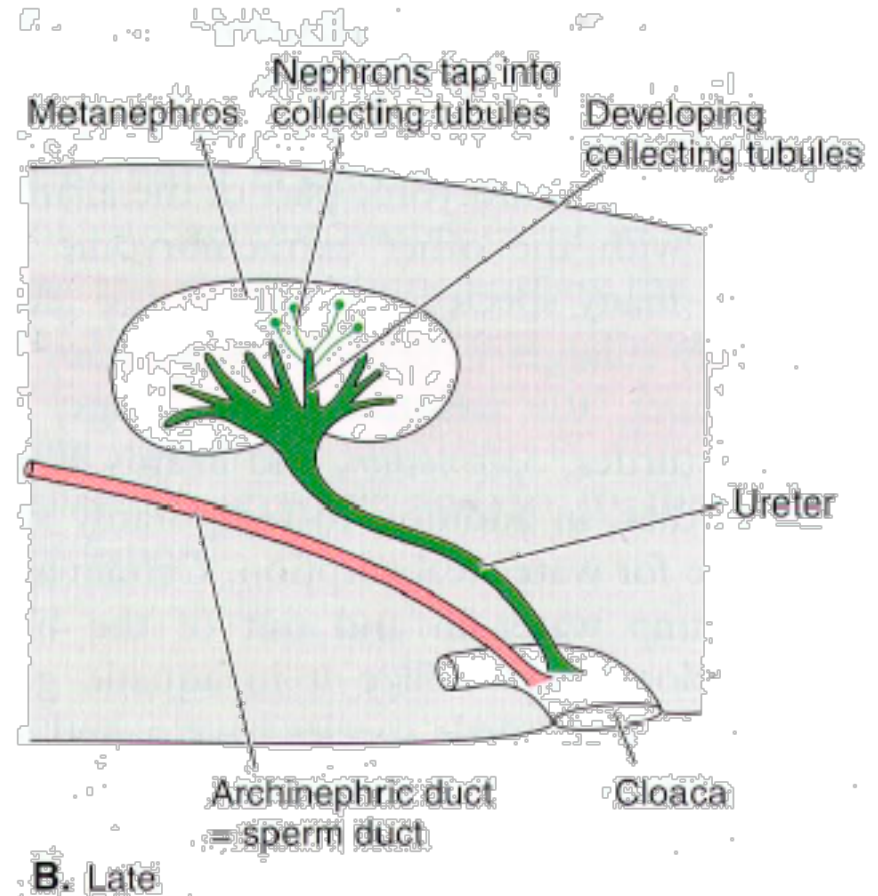

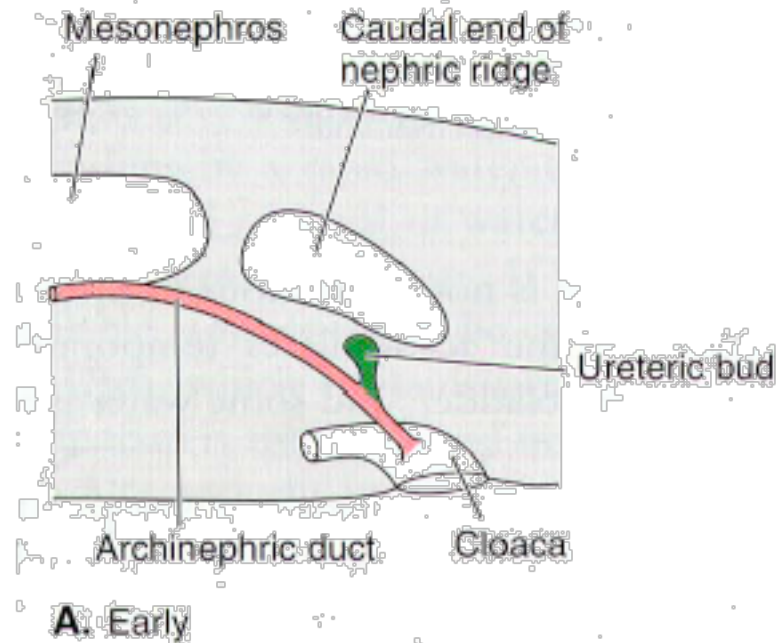

**Mesonephros is functional in frogs and birds**

C. Metanephros in late embryo and adult

A **metanephros** is always drained exclusively by one duct, the ureter.

In birds in reptiles the ureter separates from the **nephric duct (Wolffian duct)** and enters the **cloaca**. In mammals, the ureter separates from the nephric duct and enters the bladder

renal development begins when the **ureteric bud** invades kidney mesenchyme (**the metanephric blastema**)

As the embryo grows, the **ureters lengthen**, and the **kidneys rotate** and **ascend** along the dorsal body wall

## The kidney is radially patterned

- branching morphogenesis and nephron formation last until just after birth
- occur exclusively in the peripheral domain beneath the renal capsule
- new generations of nephrons and ureter branches displace older generations inward
- further differentiation occurs in inner domains at a distance from the renal capsule

# Nephron formation

From "The Kidney

**Mesenchymal nephron progenitors aggregate at ub tips and transdifferentiate into epithelial cell types that comprise the nephron**

**RECIPROCAL SIGNALING BETWEEN STROMA, NEPHRON PROGENITORS AND URETERIC BUD TIPS GIVES RISE TO CELL TYPES IN THE MATURE KIDNEY**

**nephron progenitors** NEPHRONS

**ureteric bud tips** COLLECTING DUCT SYSTEM

**stroma** CAPSULE/INTERSTITIUM

Melissa Little Lab

Nephron progenitors form nephrons

The ureteric bud forms the CD system

**Nephron  
progenitor**

**Ureteric  
bud**

**Reciprocal Signaling is required for branching morphogenesis and  
for nephron differentiation**

co-culture experiments demonstrate reciprocal signaling between ureteric bud epithelial and nephron progenitors

- no ureteric bud, nephron progenitors undergo apoptosis

from: The kidney: Eds, Vize et al., 2003)

- no nephron progenitors, no branching morphogenesis

signals from the ureteric bud control nephron induction

signals from nephron progenitors control branching morphogenesis

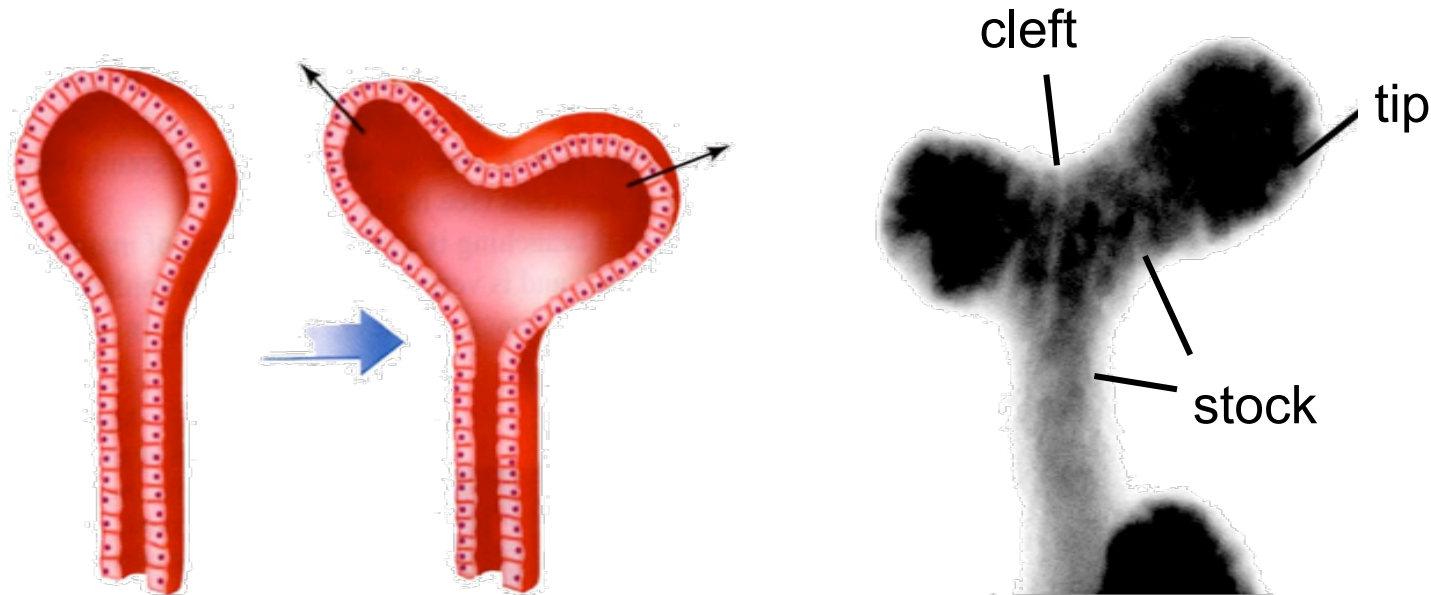

The collecting duct system grows from the periphery by **dichotomous branching**

at birth:

Hoxb7-Gfp expression showing the mouse collecting duct system

shape changes, local proliferation and remodeling at ureteric bud tips forms an **ampulla**

Branching morphogenesis:

- ampullae form at ureteric bud tips
- a cleft forms and the tips begin to bifurcate
- the tips elongate
- new ampullae form

## Branching morphogenesis in Real time

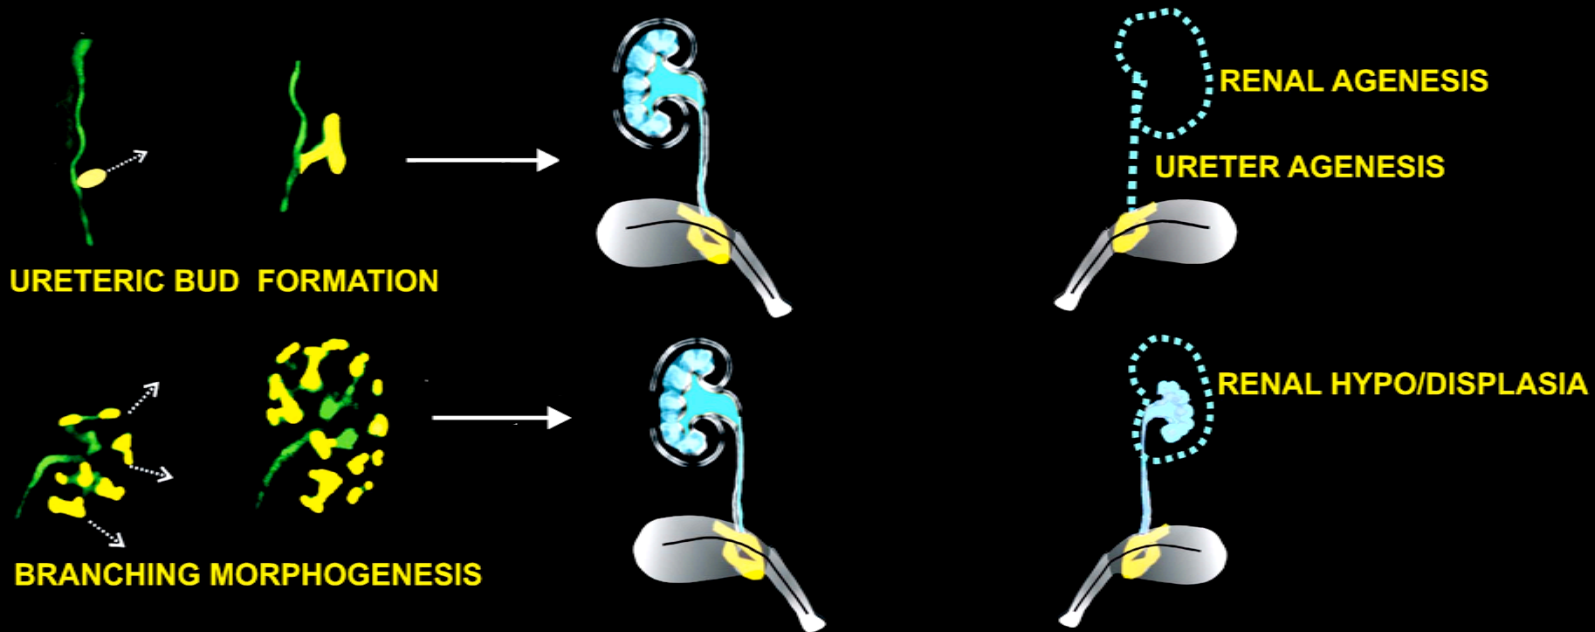

Costantini Lab  
Columbia University, Dept. of Genetics &  
Development

RET-Gdnf signaling is crucial for branching morphogenesis

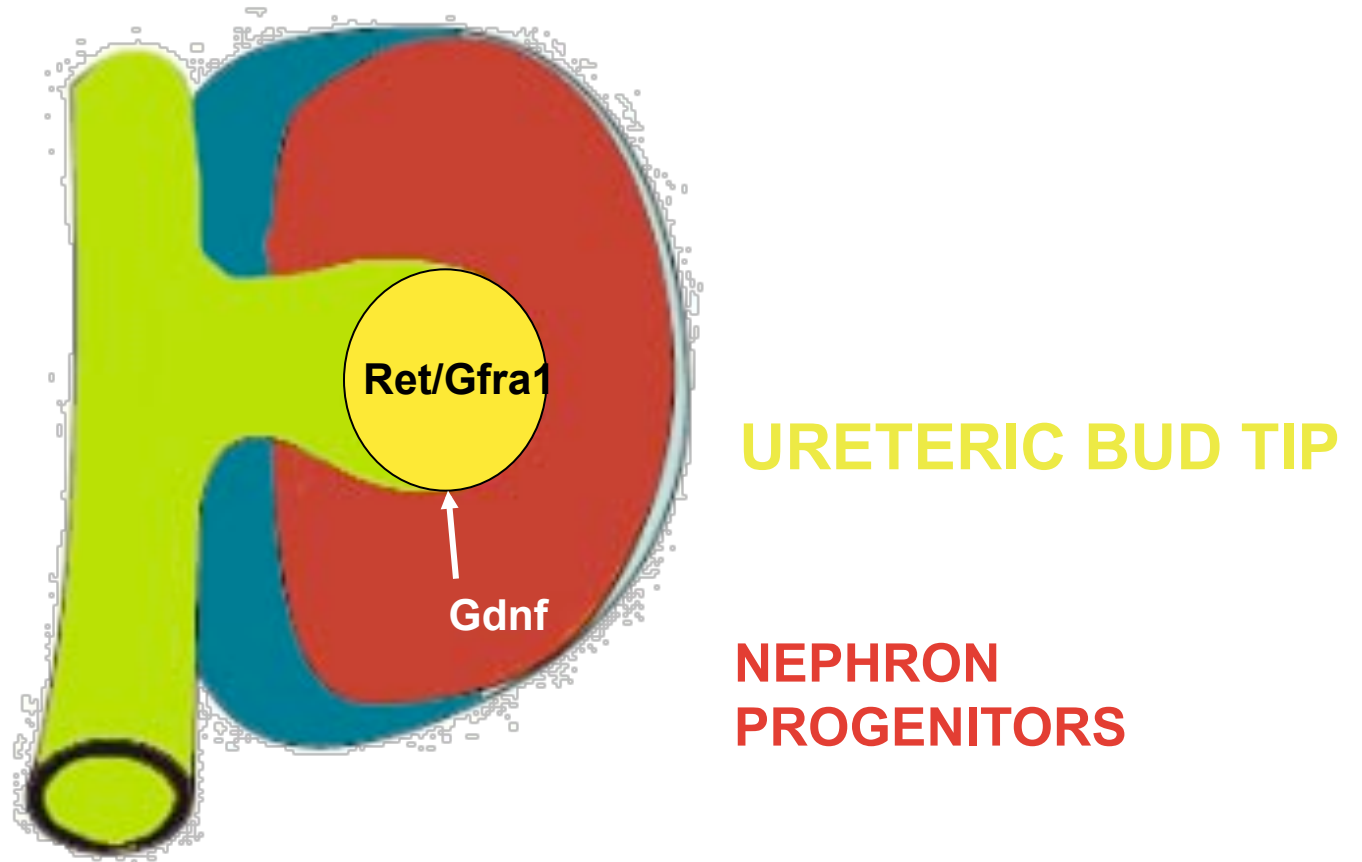

Ret mutations in humans cause renal abnormalities, Hirschsprung's disease and cancer

**GDNF signals through GFRa-1 and RET**

Mutations in Ret, Gdnf or Gfra1 result in renal agenesis or hypoplasia

**Gdnf secreted by nephron progenitors binds to Ret via the Ret co-receptor (Gfra1) inducing branching**

**STROMAL CELLS SECRETE RETINOIC ACID THAT IS REQUIRED FOR BRANCHING AND RET EXPRESSION IN UB TIPS**

# TIME-LAPSE PHOTOGRAPHY OF HOXB7-GFP KIDNEYS GROWN WITH AND WITHOUT RA

RA

Control

**AMPULLA FORMATION DEPENDS ON RA**

# Retinoic acid controls ureteric bud patterning

+Retinoic acid 72h

-Retinoic acid 72h

*Ret* expression in the ureteric bud depends on Retinoic acid

**STROMAL CELL SECRETE RETINOIC ACID  
RETINOIC ACID INDUCES RET EXPRESSION IN NEARBY URTERIC BUD CELLS**

ureteric bud (RET)

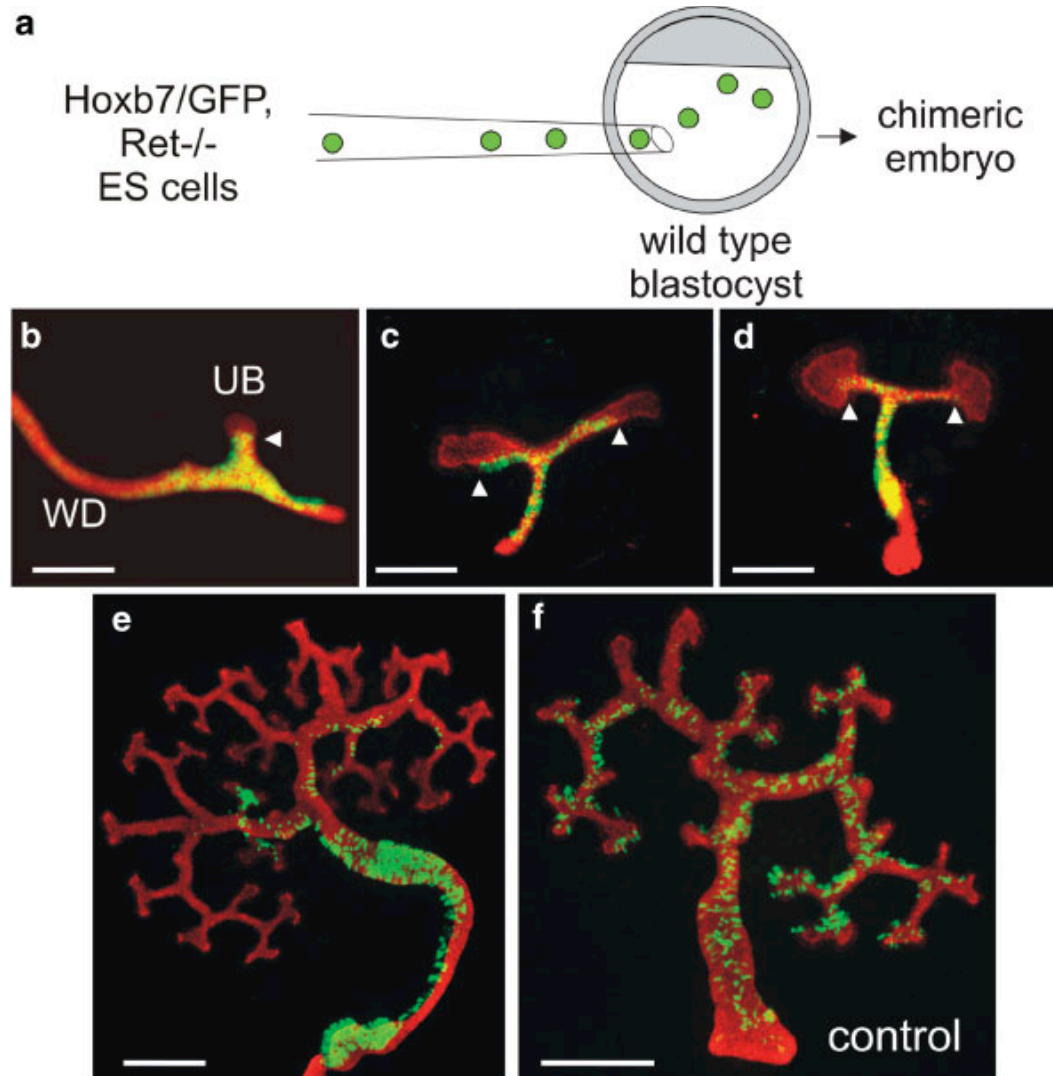

stroma (vitamin A)

**RA secreted from stromal cells controls Ret expression  
In the ureteric bud**

How does Ret signaling control branching?

ureteric bud cells must express Ret to contribute to a tip

Ret null cells are excluded from the tip domain-  
Presence in the tip depends on levels of Ret-Gdnf signaling?

How do nephrons form?

# Nephron formation

From "The Kidney

**Mesenchymal nephron progenitors aggregate at ub tips and transdifferentiate into epithelial cell types that comprise the nephron**

NEPHRONS FORM EXCLUSIVELY AT URETERIC BUD TIPS IN RESPONSE TO LOCAL SIGNALS FROM URETERIC BUD CELLS

**Nephron**  
**progenitors** condense at ub tips, **aggregate**

*TRENDS in Cell Biology*

and **trans-differentiate** into epithelial cells  
that make up the **renal vesicle**, **Comma** and **S-shaped bodies**

Nephron polarity is established at early stages

# Notch signaling controls nephron patterning along the P-D axis

Notch activation: Delta, jagged or serrate ligands on an adjacent cell bind Notch. The intracellular domain of Notch is cleaved, goes to the nucleus and induces transcriptional activation of Notch target genes.

Cheng et al, 2007

Notch2 is expressed in the developing nephron;  
Glomerular differentiation is arrested in Notch 2 mutant mice

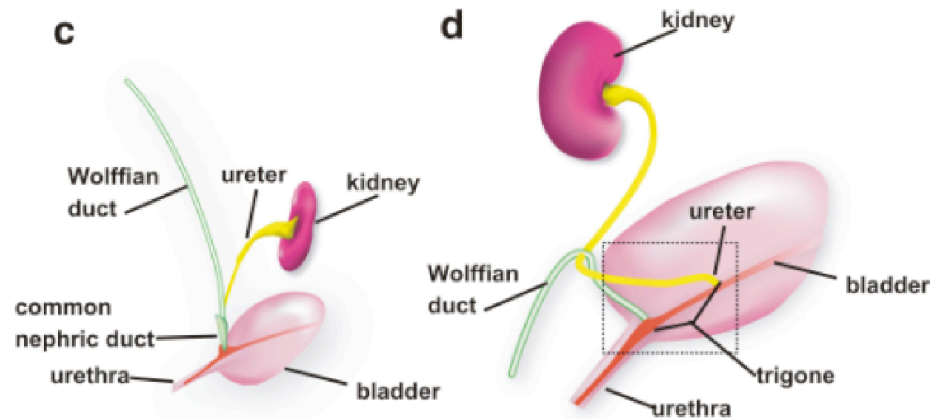

## Part II. The lower urinary tract

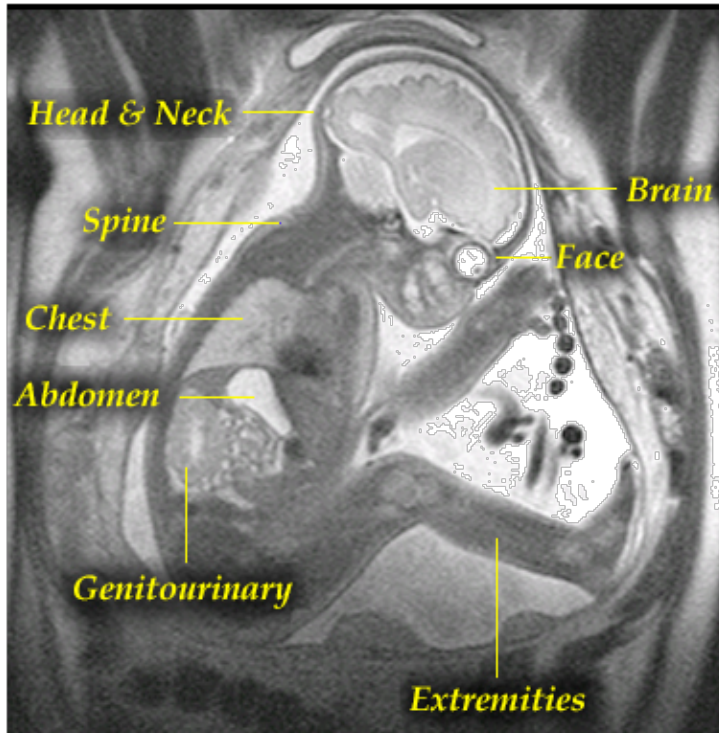

nephrons in the kidney generate urine that is propelled to the ureters and then to the bladder for storage and excretion

Wolffian duct/ureter/common nephric duct epithelium  
Bladder/urethral epithelium

DURING DEVELOPMENT THE URETER MOVES FROM THE WOLFFIAN DUCT TO THE BLADDER

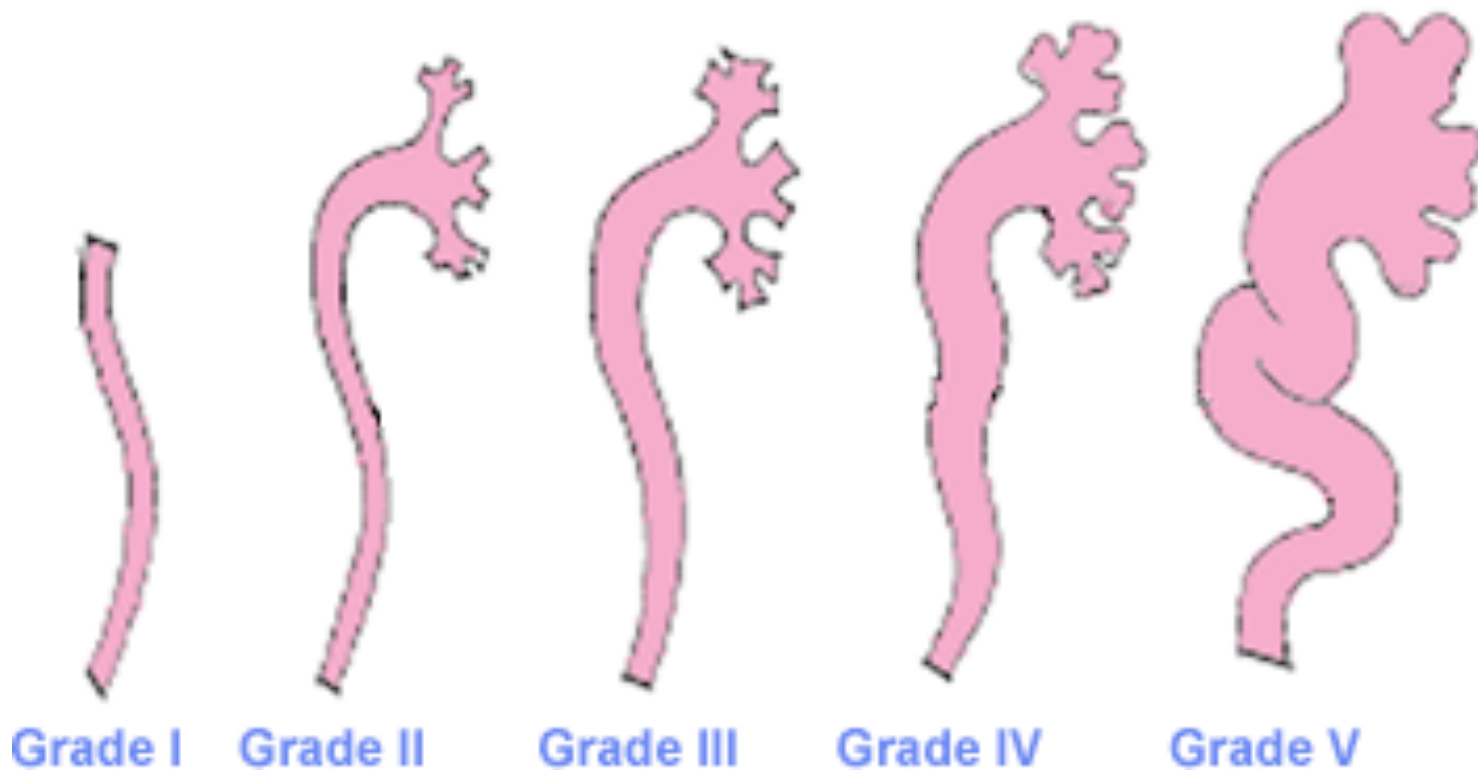

hydronephrosis *in utero*

Defective ureter insertion can cause obstruction and damage the kidney

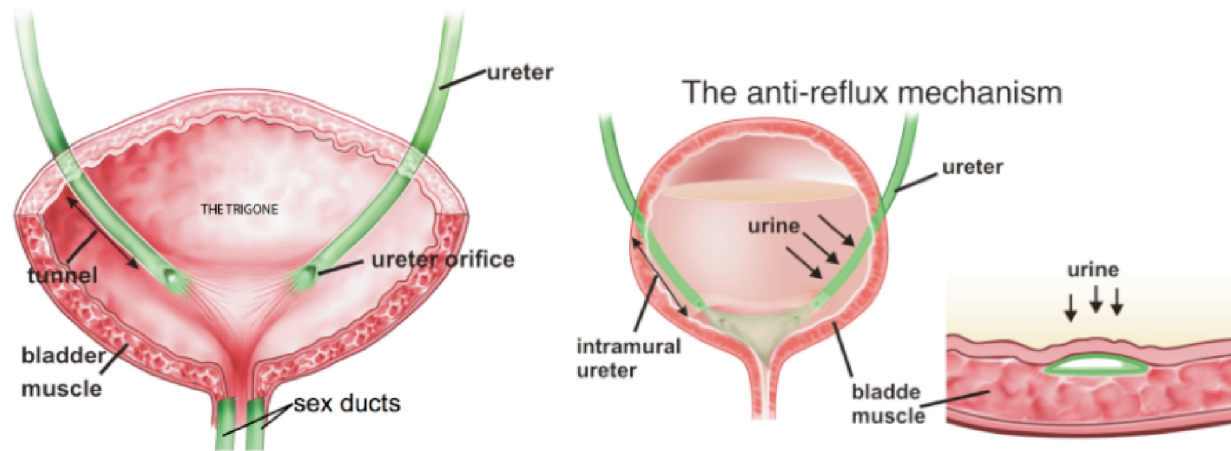

# International Reflux Classification

**Color** indicates the degree of reflux up the ureter and the calyces (i.e. the area where urine collects in the kidney).

**Severe reflux can cause end stage renal disease**

The trigone is the site of the anti-reflux mechanism

the **ureteral valve** is part of the trigone and is an **anti-reflux** mechanism that prevents urine back flow (reflux)

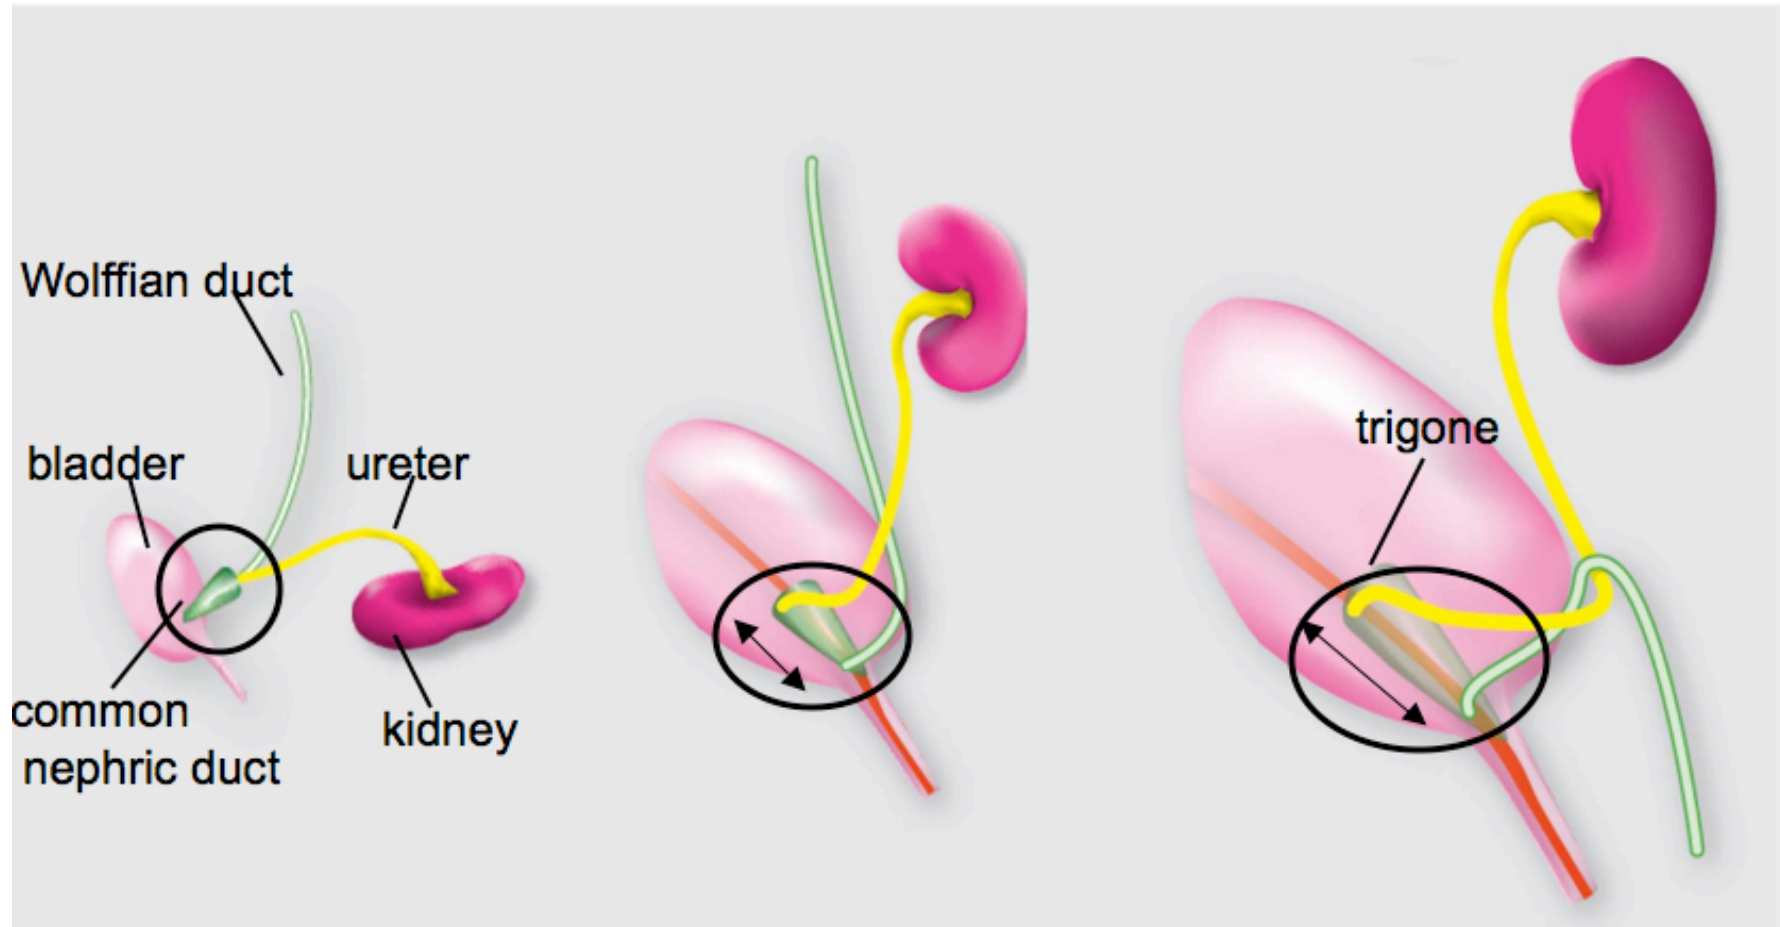

**smooth muscle**  
**ureter epithelium**  
**actin**

Ureteral valve function depends on insertion of the ureter orifice at the proper position in the bladder neck (**trigone**)

The trigone contains an anti-reflux valve

THE **TRIGONE** IS MORPHOLOGICALLY DISTINCT FROM THE BLADDER AND IS THOUGHT TO BE DERIVED FROM THE **COMMON NEPHRIC DUCT**

## Accepted model of ureter transposition

formation of the **trigone** from the **common nephric duct** repositions the ureters in the bladder

Abnormal connections between the ureter orifice and trigone are associated with vesicoureteral reflux and obstruction

normal ureter formation

ureteric bud forms too low/early

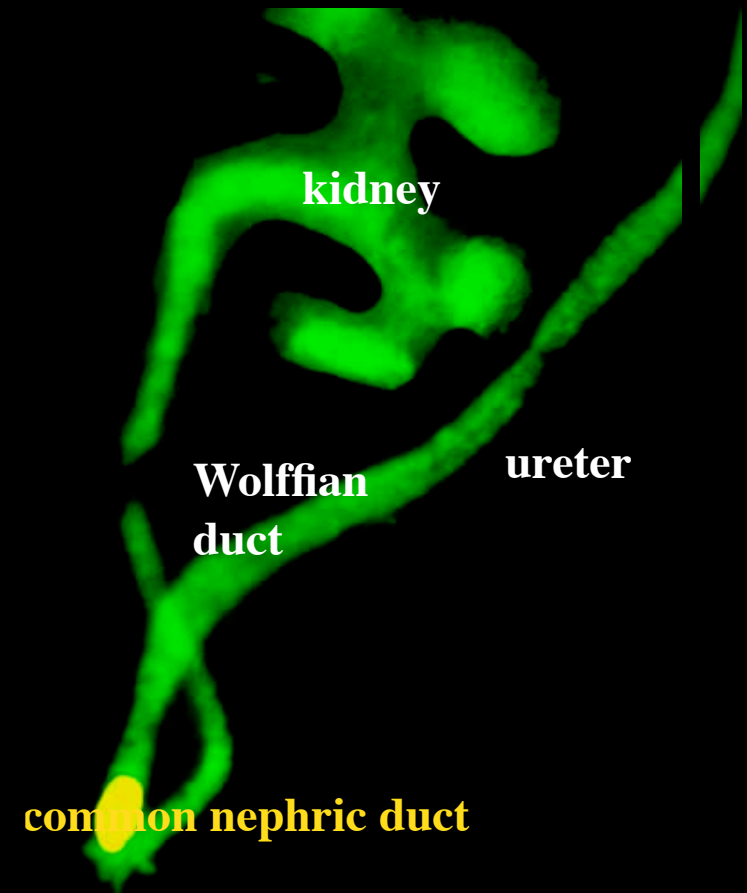

ureteric bud forms too high/late

Mackie-Stephens hypothesis: the final position of the ureter with respect to the Trigone depends on the site of its formation on the Wolffian duct

Test the Mackie Stephens hypothesis experimentally

using mouse models to re-assess the mechanism of ureter transposition:

expression of green fluorescent protein in the mouse common nephric duct enables us to follow its fate during ureter insertion

what happens to the common nephric duct during ureter transposition?

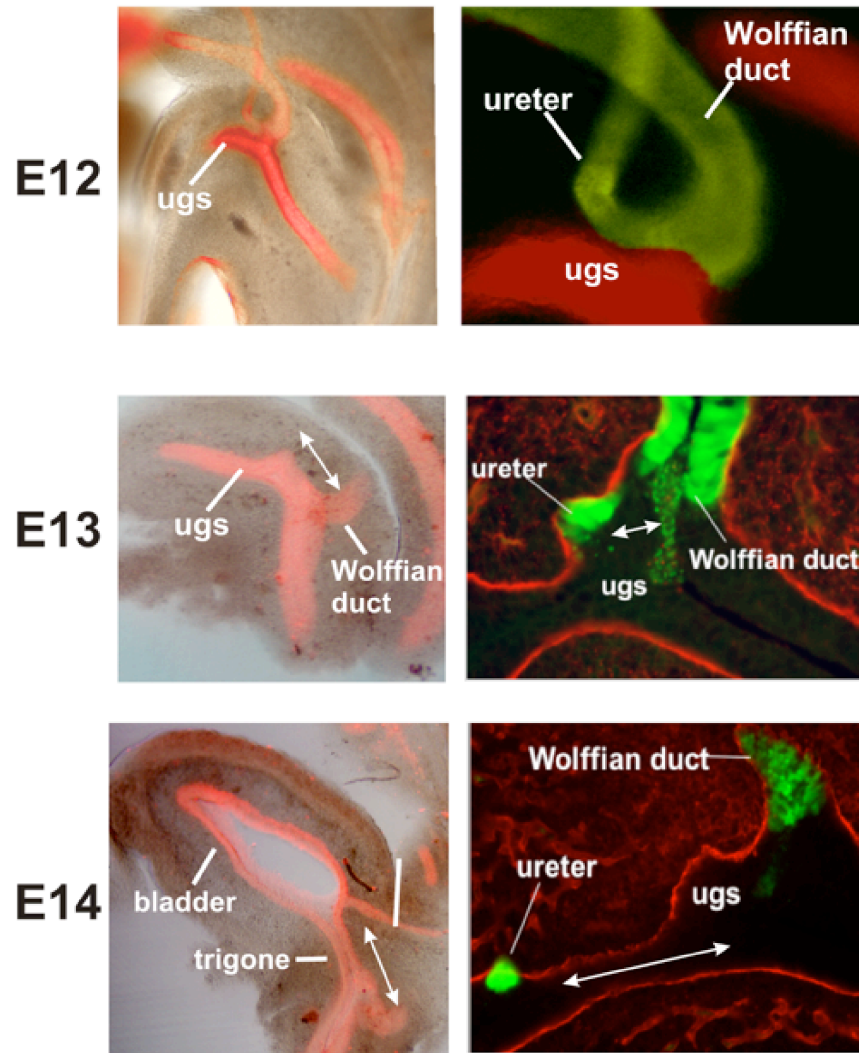

The common nephric duct appears to regress rather than expand

**CND cells are absorbed into the urogenital sinus epithelium**

**THE CND UNDERGOES APOPTOSIS AND IS UNLIKELY  
TO FORM THE BLADDER TRIGONE**

**APOPTOSIS OF THE CND ENABLES THE URETER TO  
SEPARATE AND REPOSITION IN THE BLADDER**

**ONCE THE CND UNDERGOES APOPTOSIS THE URETER ORIFICE FUSES WITH THE BLADDER EPI AND IS MOVED TO ITS FINAL INSERTION SITE AS THE BLADDER EXPANDS**

Ureter transposition depends on apoptosis of the  
**common nephric duct**

# A revised model of ureter transposition

**the common nephric duct is absorbed into the expanding urogenital sinus. The ureter makes direct contact with and inserts into the urogenital sinus**

**apoptosis of the common nephric duct enables the ureter orifice to detach from the Wolffian duct**

**continued growth and expansion of the urogenital sinus moves the ureter orifice further anterior to the bladder neck**

abnormal position of the ureter orifice

Impaired retinoid signaling, Ret

sprouty, slit-2, retinoid excess

Physical vs Functional obstruction

abnormal peristalsis

sonic hedgehog (muscle)

Calcineurin B (peristalsis)

uroplakin (epithelium)

Tbx18

Intrinsic ureteral abnormalities can cause obstruction

# URETER PERISTALSIS IS MYOGENIC, MEDIATED BY SM IN THE URETERAL COAT

J. Clin. Invest. 113:1051-1058 (2004).  
Ching-Pin Chang, et al.

Impaired peristalsis is a cause of obstruction  
(functional obstruction)

- a transitional epithelium expressing **uropalakin** lines the ureters
- The ureter smooth muscle coat mediates **myogenic peristalsis**
- defective smooth muscle formation or mutations in uropalakin cause **functional obstruction**

smooth muscle actin  
uropalakin

Loss of Tbx18 results in megaureter

Airek et al.

Airek et al.

Tbx18 is selectively expressed in peri-ureteral mesenchyme where it is required for ureter radial patterning

Loss of Tbx18 expression in periureteral mesenchyme results in smooth muscle defects as well as epithelial abnormalities

The ureter is radially patterned by epithelial mesenchymal signals

What signaling pathways are important for bladder formation?

The bladder epithelium is lined with **plaques** made from **uroplakins** that form a water-proof barrier

smooth muscle of the **detrusor** and **rugae** (folds) in the urothelium allow the bladder to expand and contract

Larsen's Embryology, 6th Edition

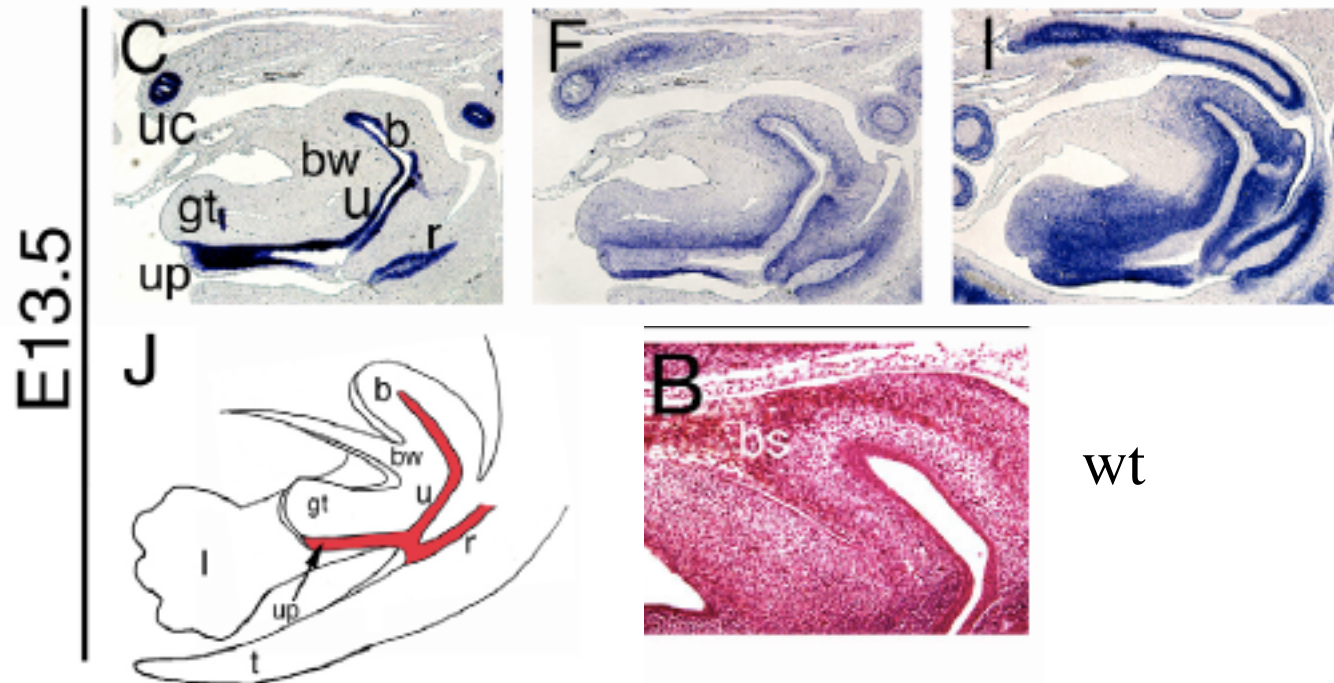

from: The kidney: Eds, Vize et al., 2003)

The **urorectal septum** partitions the **cloaca** into the **urogenital sinus** (ventral) and **hindgut** (dorsal)

The urogenital sinus forms the **bladder** and **urethra** in both sexes

Sonic Hedgehog is localized in the bladder/urethral epi  
 Patched and Gli1, downstream shh targets are localized in bladder/urethral mes

Haraguchi et al., 2007

**Shh is required for bladder formation**
